More particularly, the present invention relates to a method of forming an electrical fuse having a thin, conductive layer and a metal-oxide layer on opposite surfaces of a glass substrate and an electrical fuse using the method. Electrical fuses, which are used in semiconductor devices, are usually employed as elements for programming or erasing nonvolatlely stored data in the semiconductor devices. An electrical fuse is typically manufactured by forming an amorphous or polycrystalline silicon layer on a substrate surface and patterning the formed silicon layer to form a fuse portion, namely, a conductive pattern. Additionally, an electrical fuse is typically manufactured by forming a conductive silicon layer or a polysilicon layer on a substrate surface, an insulating material layer is formed to cover the conductive layer, and the insulating layer is patterned to form an opening exposing the conductive layer. The conductive layer is then etched to form a fuse portion. The electrical fuse is typically connected between a bit line, which is used to transmit data, and a node, which is used to read data from or write data to, a semiconductor device such as a flash memory device or a static random access memory (SRAM) device. The electrical fuses, which are widely employed in electronic circuits and memories, are made of conductive layers, for example
